Immersion and Invariance Stabilization of Nonlinear Systems: A Horizontal Contraction Approach

Lei Wang¹, Fulvio Forni², Romeo Ortega³, and Hongye Su⁴

Abstract—The main objective of this paper is to propose an alternative procedure to carry out one of the key steps of immersion and invariance stabilising controller design. Namely, the one that ensures attractivity of the manifold whose internal dynamics contains a copy of the desired system behaviour. Towards this end we invoke *contraction theory* principles and ensure the attractivity of the manifold rendering it *horizontally contractive*. The main advantage of adopting this alternative approach is to make more systematic the last step of the design with more explicit degrees of freedom to accomplish the task. The classical case of systems in feedback form is used to illustrate the proposed controller design.

Index Terms—Stabilization; contraction; nonlinear systems.

I. INTRODUCTION

Immersion and invariance (I&I) is a controller design technique that has been recently proposed in the literature to stabilise non-linear systems [1]—see also the recent book [2] where many applications of the technique are presented. The I&I approach captures the desired behaviour of the system to be controlled by introducing a target dynamical system. Then, a suitable stabilizing control law is designed to guarantee that the controlled system asymptotically behaves like the target system. More precisely, the I&I methodology relies on finding a manifold in the plants state–space that can be rendered *invariant and attractive* by feedback control, such that (i) on the manifold, the closed loop dynamics behaves like the desired dynamics (ii) away from the manifold, the control law steers the state of the system towards the manifold. The usual way to carry out the latter step is to define an extended dynamical system given by a copy of

the plant and by a new *error* dynamics, denoted by the coordinate z , that measures the distance to the manifold. Then, a full–state feedback controller must be designed to ensure boundedness of the plant state and convergence to zero of the z coordinate. The main stabilisation result in I&I states that the evaluation of this control law on the manifold defines an asymptotically stabilising controller for the system. The construction leads to a static controller, since the control law is a function only of the plant state.

The design of the aforementioned full–state feedback controller is not systematic and finding a controller that renders the desired manifold attractive could be challenging in practice. The main objective of this paper is to carry out this step by exploiting *contraction theory* principles [6]. More precisely, we will use *horizontal contraction* [4] to draw geometric conditions that guarantee the attractiveness of the desired manifold. The main advantage of adopting this alternative approach in I&I is to make more systematic the design of the control action away from the desired manifold. We anticipate that the stabilization of the extended system of I&I is replaced by the stabilization of the prolonged system [3], defined by the plants and its linearization. In comparison to I&I, the local nature of the approach pursued in this paper provides more degrees of freedom in the design of the controller, possibly widening the use of I&I in applications.

The paper is organized as follows. Section II briefly recalls the standard I&I controller design procedure. The novel design based on horizontal contraction is illustrated in Section III. The section provides the main result of the paper, whose proof is in Appendix B. The classical example of systems in feedback form is presented in Section IV. Concluding remarks are detailed in Section V. Appendix A contains a counterexample to the classical I&I design. This minor issue of the classical I&I is easily fixed by enforcing a simple extra assumption.

Notation For $x \in \mathbb{R}^n$ we denote the Euclidean norm $|x|^2 := x^\top x$. Given a function $f : \mathbb{R}^n \rightarrow \mathbb{R}$ we define the differential operators

$$\nabla f := \left(\frac{\partial f}{\partial x} \right)^\top, \quad \nabla_{x_i} f := \left(\frac{\partial f}{\partial x_i} \right)^\top,$$

where $x_i \in \mathbb{R}^p$ is an element of the vector x . For a mapping $g : \mathbb{R}^n \rightarrow \mathbb{R}^m$, its Jacobian matrix is defined as

$$\nabla g := \begin{bmatrix} (\nabla g_1)^\top \\ \vdots \\ (\nabla g_m)^\top \end{bmatrix},$$

where $g_i : \mathbb{R}^n \rightarrow \mathbb{R}$ is the i -th element of g . When clear from the context the subindex of the operator ∇ and the arguments of the functions will be omitted. All the functions in the paper are assumed sufficiently smooth.

II. THE STANDARD I&I STABILISATION PROCEDURE

Consider the system

$$\dot{x} = f(x) + g(x)u \quad (1)$$

with state $x \in \mathbb{R}^n$, the input control $u \in \mathbb{R}^m$, and an assignable equilibrium point

$$x_* \in \{x \in \mathbb{R}^n \mid g^\perp(x)f(x) = 0\}$$

to be *stabilized*, where $g^\perp : \mathbb{R}^n \rightarrow \mathbb{R}^{(n-m) \times m}$ is a full-rank left annihilator of $g(x)$. Stabilisation is achieved in I&I fulfilling the following four steps. The reader is referred to [2] for the proof of the next proposition

Proposition 1: Assume that there exist mappings

$$\begin{aligned} \alpha : \mathbb{R}^p \rightarrow \mathbb{R}^p, \quad \pi : \mathbb{R}^p \rightarrow \mathbb{R}^n, \quad c : \mathbb{R}^n \rightarrow \mathbb{R}^m, \\ \phi : \mathbb{R}^n \rightarrow \mathbb{R}^{n-p}, \quad v : \mathbb{R}^n \times \mathbb{R}^{n-p} \rightarrow \mathbb{R}^m, \end{aligned}$$

with $p < n$, such that the following hold.

(A1) (*Target system*) The system

$$\dot{\xi} = \alpha(\xi), \quad (2)$$

has a globally asymptotically stable equilibrium at $\xi_* \in \mathbb{R}^p$ and $x_* = \pi(\xi_*)$.

(A2) (*Manifold invariance condition*) For all $\xi \in \mathbb{R}^p$,

$$f(\pi(\xi)) + g(\pi(\xi))c(\pi(\xi)) = \nabla\pi(\xi)\alpha(\xi). \quad (3)$$

(A3) (*Implicit manifold description*) The following set identity holds

$$\mathcal{M} := \{x \in \mathbb{R}^n \mid x = \pi(\xi)\} = \{x \in \mathbb{R}^n \mid \phi(x) = 0\}. \quad (4)$$

(A4) (*Manifold attractivity and trajectory boundedness*) Consider the system

$$\dot{x} = f(x) + g(x)v(x, z) \quad (5)$$

$$\dot{z} = \nabla\phi(x)[f(x) + g(x)v(x, z)], \quad (6)$$

with the initial condition constraint

$$z(0) = \phi(x(0)), \quad (7)$$

and $v(x, z)$ verifying

$$v(\pi(\xi), 0) = c(\pi(\xi)), \quad \forall \xi \in \mathbb{R}^p. \quad (8)$$

All trajectories of the system are bounded and satisfy

$$\lim_{t \rightarrow \infty} z(t) = 0. \quad (9)$$

Then, x_* is a *globally asymptotically stable* (GAS) equilibrium of the closed-loop system

$$\dot{x} = f(x) + g(x)v(x, \phi(x)). \quad (10)$$

┘

Following the discussion in the introduction, the accomplishment of step (A4) is not systematic and may challenge

the successful completion of the I&I design. Exploiting [4], we propose in the next section to replace (A4) by a novel condition based on horizontal contraction [4].

Remark 1: In comparison to the results presented in [1], [2], we have added the initial condition constraint (7) and the requirement (8). The first condition ensures that $z(t) = \phi(x(t))$, $\forall t \geq 0$, while the second one guarantees that the x -system behaves like the ξ -system when restricted to the manifold \mathcal{M} . These requirements were implicitly assumed in previous works. If these conditions are not imposed it is possible to show that the claim of Proposition 1 is false. An example of this fact is given in Appendix A. ┘

Remark 2: The I&I technique makes contact with the literature of invariant manifolds stability [8] and of conditional stability (relative to a set) [7]. Indeed, in the I&I technique the action of a state-feedback controller renders invariant and stabilizes a suitable submanifold of the system state space while enforcing a desired steady-state behavior, represented by the target dynamics. ┘

III. THE I&I HORIZONTAL CONTRACTION PROCEDURE

The proposition below proposes to replace the step (A4) in Proposition 1 by a horizontal contraction based design that ensures attractivity of the manifold \mathcal{M} .

Proposition 2: Given the conditions (A1)–(A3) in Proposition 1, assume there exist mappings

$$\begin{aligned} P : \mathbb{R}^n \rightarrow \mathbb{R}^{(n-p) \times (n-p)}, \quad P = P^T > 0 \\ R : \mathbb{R}^n \rightarrow \mathbb{R}^{(n-p) \times n}, \\ \beta : \mathbb{R}^n \rightarrow \mathbb{R}^m, \\ \rho : \mathbb{R}^n \rightarrow \mathbb{R}, \quad \rho > 0, \end{aligned}$$

such that the following holds.

(A4*) (*Manifold attractivity via horizontal contraction*)

(i) For all $x \in \mathbb{R}^n$, $R(x)$ is full rank and

$$R(\pi(\xi)) = \nabla\phi(\pi(\xi)), \quad \forall \xi \in \mathbb{R}^p. \quad (11)$$

(ii) For all $\xi \in \mathbb{R}^p$

$$\beta(\pi(\xi)) = c(\pi(\xi)).$$

(iii) The candidate Finsler-Lyapunov function $V : \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}_{\geq 0}$ given by

$$V(x, \delta x) := \delta x^\top R^\top(x)P(x)R(x)\delta x, \quad (12)$$

satisfies

$$\dot{V}(x, \delta x) \leq -\rho(x)V(x, \delta x) \quad (13)$$

along the trajectories of the prolonged system

$$\dot{x} = f(x) + g(x)\beta(x) \quad (14)$$

$$\dot{\delta x} = \nabla[f(x) + g(x)\beta(x)]\delta x. \quad (15)$$

(iv) The trajectories of (14) are *bounded*.

Then, x_* is a GAS equilibrium point of the closed-loop system (14). Furthermore, if the fixed point ξ_* of the target system (2) is hyperbolic, then x_* is hyperbolic. ┘

Remark 3: A natural simple choice for $R(x)$ is $\nabla\phi(x)$, provided that $\nabla\phi(x)$ is full rank for all $x \in \mathbb{R}^n$. ┘

Remark 4: In contrast with the classical I&I Proposition 2 directly provides the static state–feedback controller $\beta(x)$. This should be compared with the control $v(x, z)$ that should verify condition (A4) for the augmented system (5), (6), which is later evaluated on the manifold to generate the actual control to be applied, that is, $v(x, \phi(x))$. \lrcorner

Remark 5: Proposition 2 can be formulated in a similar way for any forward invariant region $\mathcal{C} \subseteq \mathbb{R}^n$. If $\mathcal{C} = \mathbb{R}^n$ then, as stated in the proposition, one gets GAS. Otherwise, one gets regional stability. This formulation may be useful in applications when global results are difficult to achieve or when the system lives in a manifold different from \mathbb{R}^n . Note that if \mathcal{C} is compact, then the condition (iv) of boundedness of trajectories is automatically satisfied. \lrcorner

IV. APPLICATION TO SYSTEMS IN FEEDBACK FORM

Consider the class of systems in feedback form described by the equations

$$\begin{aligned}\dot{x}_1 &= f(x_1, x_2), \\ \dot{x}_2 &= u,\end{aligned}\quad (16)$$

with $x := \text{col}(x_1, x_2) \in \mathbb{R}^n \times \mathbb{R}$, and $u \in \mathbb{R}$. Consistent with the standard backstepping scenario [5] assume there exists a mapping $\pi_2 : \mathbb{R}^n \rightarrow \mathbb{R}$ such that the system

$$\dot{x}_1 = f(x_1, \pi_2(x_1))$$

has a GAS equilibrium at the origin. A sensible choice of the target dynamics is then given by

$$\dot{\xi} = f(\xi, \pi_2(\xi)), \quad (17)$$

and this implies that the mapping $\pi(\xi)$ has the form

$$\pi(\xi) = \begin{bmatrix} \xi \\ \pi_2(\xi) \end{bmatrix}.$$

To verify Assumptions (A2) and (A3) of Proposition 1 we can choose

$$c(\xi, \pi_2(\xi)) = \nabla \pi_2(\xi) f(\xi, \pi_2(\xi)) \quad (18)$$

$$\phi(x) = x_2 - \pi_2(x_1), \quad (19)$$

which clearly satisfy (3) and (4).

The differential relation of the system (16) in closed-loop with the control $\beta(x)$ is

$$\delta \dot{x} = \begin{bmatrix} \nabla_{x_1} f(x) & \nabla_{x_2} f(x) \\ \nabla_{x_1} \beta(x) & \nabla_{x_2} \beta(x) \end{bmatrix} \delta x =: Q(x) \delta x,$$

From Proposition 2 we select $R(x) = \nabla \phi(x)$ and $P(x) = I$. Whence the Finsler–Lyapunov function (12) takes the form

$$V(x, \delta x) = \delta x^\top M(x_1) \delta x, \quad (20)$$

where we have defined

$$\begin{aligned}M(x_1) &:= \begin{bmatrix} \nabla \phi(x)^\top \nabla \phi(x) \\ \nabla \pi_2(x_1) [\nabla \pi_2(x_1)]^\top & -\nabla \pi_2(x_1) \\ -[\nabla \pi_2(x_1)]^\top & 1 \end{bmatrix} \\ &= \end{aligned}\quad (21)$$

Fixing $\rho(x) = k > 0$ the condition (13) is satisfied if and only if

$$\dot{M}(x_1) + M(x_1) \left[Q(x) + \frac{k}{2} I \right] + \left[Q^\top(x) + \frac{k}{2} I \right] M(x_1) \leq 0. \quad (22)$$

We are in position to state the following proposition.

Proposition 3: Consider a system described by equations of the form (16) and suppose there exist mappings $\pi_2 : \mathbb{R}^n \rightarrow \mathbb{R}$ and $\beta : \mathbb{R}^{(n+1)} \rightarrow \mathbb{R}$ such that the following holds.

(a) The system

$$\dot{x}_1 = f(x_1, \pi_2(x_1))$$

has a GAS equilibrium at zero.

(b) The inequality (22) is satisfied for some $k > 0$.

(c) For all $\xi \in \mathbb{R}$

$$\beta(\xi, \pi_2(\xi)) = \nabla \pi_2(\xi) f(\xi, \pi_2(\xi)).$$

Then, the system (16) in closed-loop with $\beta(x)$ has a GAS equilibrium at zero. \lrcorner

Example 1: To illustrate the result in Proposition 3, consider the two-dimensional system

$$\begin{aligned}\dot{x}_1 &= -x_1 + \lambda x_1^3 x_2 \\ \dot{x}_2 &= u,\end{aligned}\quad (23)$$

in which $\lambda > 0$. We proceed now to verify condition (a). Selecting $\pi_2(x_1) = -x_1^2$ we obtain

$$\dot{x}_1 = f(x_1, \pi_2(x_1)) = -x_1 - \lambda x_1^5$$

which has a GAS equilibrium at zero. To check condition (b) we, first, compute

$$\begin{aligned}\phi(x) &= x_1^2 + x_2 \\ M(x) &= \begin{bmatrix} 4x_1^2 & 2x_1 \\ 2x_1 & 1 \end{bmatrix} \\ Q(x) &= \begin{bmatrix} -1 + 3\lambda x_1^2 x_2 & \lambda x_1^3 \\ \nabla_{x_1} \beta(x) & \nabla_{x_2} \beta(x) \end{bmatrix}.\end{aligned}$$

Some lengthy, but straightforward calculations, show that

$$\beta(x) = -\frac{1}{2}(k-4)x_1^2 - \frac{1}{2}kx_2 - 2\lambda x_1^4 x_2 \quad (24)$$

solves (22) with identity. It only remains to verify condition (c), which holds true because

$$\beta(\xi, \pi_2(\xi)) = 2\xi^2(1 + \lambda\xi^4) = \underbrace{(-2\xi)}_{\nabla \pi_2(\xi)} \underbrace{[-\xi + \lambda\xi^3(-\xi^2)]}_{f(\xi, \pi_2(\xi))}.$$

In conclusion, the system (23) in closed-loop with the control (24) has a GAS equilibrium at the origin. \lrcorner

V. CONCLUSIONS

An alternative procedure to complete the design of I&I controllers for stabilization of nonlinear systems has been proposed. The central idea is to replace by a contraction-based design the stabilization step on the extended dynamics (5),(6) required by condition (A4) of the I&I procedure. The main advantage of the contraction-based approach is to render more systematic the design and to give more degrees

of freedom for its accomplishment. The key step of the novel design is the use of horizontal Finsler–Lyapunov functions [4] that decays along the trajectories of the prolonged system, in the spirit of classical Lyapunov theory. Of course, similarly to all constructive procedures for the design of nonlinear controllers or observers, for the successful application of the novel design proposed by the paper it is necessary to solve a partial differential equation. In particular, for systems in feedback form, it is necessary to find a controller $\beta(x)$ that satisfies (22) ($\beta(x)$ is encoded in $Q(x)$) for a suitable choice of $R(x)$ and P .

From the conceptual viewpoint, the use of Finsler–Lyapunov functions replaces the stabilization of the off-manifold coordinate z of I&I with the horizontal stabilization of the linearization along trajectories. For instance, the method proposed in this paper stabilizes the *linearization* of the system along suitable directions of its tangent space, thus providing a local and intrinsic feedback design procedure that does not require any a-priori definition of the off-manifold coordinate z . The advantage is a more general design method, possibly. This generality is directly encoded into the conditions of Proposition 2: the z coordinate of classical I&I is replaced at local level by the matrix $R(x)$, which is one of the free parameters to be selected in the formulation of the partial differential equation (22) ($M(x)$ depends on $R(x)$). The intrinsic nature of the design combined with the increased degrees of freedom make the present formulation of horizontal contraction–based I&I a promising stabilization tool for applications.

APPENDIX

A. Counterexample to Theorem 2.1 of [2]

Our objective in this appendix is to show that if we follow all the steps of the standard I&I procedure of Proposition 1—*without* imposing the conditions (7) and (8)—we cannot guarantee GAS of the equilibrium. Towards this end, consider the two–dimensional, linear, time–invariant system

$$\begin{aligned}\dot{x}_1 &= -x_1 + \theta + u_1 \\ \dot{x}_2 &= u_2\end{aligned}$$

where $\theta \neq 0$ is a constant parameter and $u = \text{col}(u_1, u_2)$ is the control input. The control objective is to stabilize the system at the origin using the I&I procedure.

First, we select the target system as $\dot{\xi} = -\xi$, which clearly has a GAS equilibrium at zero, verifying the first part of (A1). Selecting $\pi(\xi) = \text{col}(\xi, 0)$ it is easy to see that the manifold invariance condition (A2) holds with the constant control

$$c(\pi(\xi)) = \begin{bmatrix} -\theta \\ 0 \end{bmatrix}.$$

Moreover, $\pi(0) = \text{col}(0, 0)$, verifying the second part of (A1). The implicit manifold condition (A3) is verified with $\phi(x) = x_2$. Finally, we need to define a controller $v(x, z)$ for the augmented system

$$\begin{aligned}\dot{x}_1 &= -x_1 + \theta + v_1(x, z) \\ \dot{x}_2 &= v_2(x, z) \\ \dot{z} &= \nabla\phi(x) \begin{bmatrix} -x_1 + \theta + v_1(x, z) \\ v_2(x, z) \end{bmatrix} = v_2(x, z),\end{aligned}$$

that ensures boundedness of trajectories and $\lim_{t \rightarrow \infty} z(t) = 0$. This is clearly guaranteed with the selection

$$v(x, z) = \begin{bmatrix} 0 \\ -z \end{bmatrix}.$$

It is claimed in Theorem 2.1 of [2] that applying the control

$$u = v(x, \phi(x)) = \begin{bmatrix} 0 \\ -x_2 \end{bmatrix},$$

to the x –system ensures the origin is a GAS equilibrium. But the resulting closed–loop system

$$\begin{aligned}\dot{x}_1 &= -x_1 + \theta \\ \dot{x}_2 &= -x_2\end{aligned}$$

has a GAS equilibrium at $(\theta, 0)$, not at the origin.

The source of the problem is that, if we do not impose in (A4) the initial condition (7) we have only that $\dot{z} = \dot{\phi} = \dot{x}_2$ but $z(t) \neq \phi(x(t)) = x_2(t)$. Indeed, integrating the system

$$\begin{aligned}\dot{x}_2 &= -z \\ \dot{z} &= -z,\end{aligned}$$

we get

$$\begin{aligned}z(t) &= e^{-t}z(0) \\ x_2(t) &= x_2(0) - \int_0^t e^{-\tau}z(0)d\tau = x_2(0) - z(0)(1 - e^{-t}).\end{aligned}\tag{25}$$

Notice that the condition (8) is also not verified since

$$v(\pi(\xi), 0) = \begin{bmatrix} 0 \\ 0 \end{bmatrix} \neq c(\pi(\xi)) = \begin{bmatrix} -\theta \\ 0 \end{bmatrix}.$$

It is clear from (25) that imposing the initial condition (7), that is, $z(0) = x_2(0)$ we get $z(t) = x_2(t)$. But we still need to modify the controller to comply with (8). A simple choice being

$$v(x, z) = \begin{bmatrix} -\theta \\ -z \end{bmatrix}.$$

For this new choice the control

$$u = v(x, \phi(x)) = \begin{bmatrix} -\theta \\ -x_2 \end{bmatrix}$$

yields $\dot{x} = -x$, which certainly has a GAS equilibrium at zero.

B. Proof of Proposition 2

The proof is divided in four parts establishing global attractivity of (I) the manifold and (II) the equilibrium point, (III) local stability and (IV) hyperbolicity of the equilibrium point.

I. Global attractiveness of \mathcal{M}

Take $|\delta x|_x := \sqrt{V(x, \delta x)}$. Given any differentiable curve $\gamma : [0, 1] \rightarrow \mathbb{R}^n$ define the horizontal length $\ell(\gamma) := \int_0^1 |\dot{\gamma}(s)|_{\gamma(s)} ds$. Note that $\ell(\gamma) \neq 0$ iff $R(\gamma(s))\dot{\gamma}(s) \neq 0$ for some $s \in [0, 1]$. Thus, $\ell(\gamma) \neq 0$ if $\gamma(s) \notin \mathcal{M}$ for some $s \in [0, 1]$. For instance, consider any x and y in \mathcal{M} . By construction, there exists a differentiable curve γ such that $\gamma(0) = x$, $\gamma(1) = y$ and $\gamma(s) \in \mathcal{M}$ for all $s \in [0, 1]$. Then $R(\gamma(s))\dot{\gamma}(s) = \nabla\phi(\gamma(s))\dot{\gamma}(s) = 0$, by (11), which implies $|\dot{\gamma}(s)|_{\gamma(s)} = 0$, thus $\ell(\gamma) = 0$. In a similar way, consider any $x \in \mathcal{M}$ and $y \notin \mathcal{M}$ and let γ be any differentiable curve such that $\gamma(0) = x$ and $\gamma(1) = y$. Then, because of the rank condition on $R(x)$ and differentiability of $R(x)$, there exists a measurable subset of $\mathcal{I} \subset [0, 1]$ such that $|\dot{\gamma}(s)|_{\gamma(s)} \neq 0$. Thus, $\ell(\gamma) > 0$.

Let $\psi_t(x_0)$ denotes the flow of the system $\dot{x} = f(x) + g(x)\beta(x)$ at time t from the initial condition $\psi_0(x_0) = x_0 \in \mathbb{R}^n$. Exploiting the boundedness of trajectories, global attractiveness of \mathcal{M} can be proven by showing that $\lim_{t \rightarrow \infty} \ell(\psi_t(\gamma)) = 0$ for any given curve γ such that $\ell(\gamma) \neq 0$. We show this in the next two paragraphs.

By boundedness of trajectories, for any $\gamma : [0, 1] \rightarrow \mathbb{R}^n$ there exists a compact set \mathcal{K} such that, $\psi_t(\gamma(s)) \in \mathcal{K}$ for each $s \in [0, 1]$ and $t \geq 0$. By continuity, for each $x \in \mathcal{K}$ and $\delta x \in \mathbb{R}^n$, (13) guarantees that there exists $\lambda > 0$ such that $\dot{V}(x, \delta x) < -\lambda V(x, \delta x) < 0$. It follows that

$$V\left(\psi_t(\gamma(s)), \frac{d}{ds}\psi_t(\gamma(s))\right) \leq \exp(-\lambda t) V\left(\gamma(s), \frac{d}{ds}\gamma(s)\right),$$

which implies that

$$\left| \frac{d}{ds}\psi_t(\gamma(s)) \right|_{\psi_t(\gamma(s))} \leq \exp\left(-\frac{\lambda t}{2}\right) \left| \frac{d}{ds}\gamma(s) \right|_{\gamma(s)}.$$

Thus, $\ell(\psi_t(\gamma)) \leq \exp(-\frac{\lambda t}{2})\ell(\gamma)$.

Suppose now that $\gamma(0) \in \mathcal{M}$ and $\gamma(1) \notin \mathcal{M}$. By (A2), $\psi_t(\gamma(0)) \in \mathcal{M}$ for all $t \geq 0$ (manifold invariance). Thus, the combination of $\lim_{t \rightarrow \infty} \ell(\psi_t(\gamma)) = 0$ with boundedness of trajectories guarantees that $\psi_t(\gamma(1))$ converges asymptotically to \mathcal{M} .

II. Global attractiveness of x_*

By (A2), (A4') and the boundedness of trajectories we have that any trajectory of the closed loop system converges to the manifold $\phi(x) = 0$. Moreover, by (A1) and (A2), the manifold is invariant and internally asymptotically stable, hence all trajectories of the closed loop system converge to the equilibrium x_* .¹

III. Local stability of x_*

To conclude the proof we need to show that x_* is Lyapunov stable. Note that any trajectory of the closed loop system is the image through the mapping $\pi(\cdot)$ of a trajectory of the target system ξ . Moreover, for any ε_1 , there exists δ_1 such that $|\xi(0)| \leq \delta_1$ implies $|\xi(t)| \leq \varepsilon_1$. Hence, by regularity of π , for any $\varepsilon > 0$ there exists $\delta > 0$ such that $|\pi(\xi(0))| \leq \delta$ implies $|\pi(\xi(t))| \leq \varepsilon$.

IV. Hyperbolicity of x_*

Without loss of generality take $x_* = 0$ and define $S := \nabla\alpha(0)$, $\Pi := \nabla\pi(0)$, and $A := \nabla[f(0) + g(0)c(0)]$. For simplicity denote the matrix $R(0)$ by R and $P(0)$ by P . The linearization of the closed loop system computed on the fixed point reads $\tilde{x} = A\tilde{x}$. $\tilde{\xi} = S\xi$ denotes the linearization of the target system at the fixed point $\xi_* = 0$.

Now, S is Hurwitz by assumption. The span of the columns of Π and R^\top define two orthogonal subspaces of the state space. To see this, note that $\Pi\tilde{\xi} \in T_{x_*}\mathcal{M}$ therefore $R\Pi\tilde{\xi} = \nabla\phi(0)\Pi\tilde{\xi} = 0$. Since ξ has dimension p , it follows that $R\Pi = 0$. Clearly, $\Pi^\top R^\top = (R\Pi)^\top = 0$. It follows that the state of the linearized closed loop system can be decomposed as

$$\tilde{x} = \Pi\tilde{\xi} + R^\top e$$

where e is a vector in $\mathbb{R}^{(n-p)}$. In particular, take

$$e := (RR^\top)^{-1}R(x - \Pi\tilde{\xi}) = (RR^\top)^{-1}R\tilde{x}.$$

The invertibility of RR^\top follows from the rank condition on R . The last identity follows from orthogonality, i.e. $R\Pi = 0$.

Take any trajectory $\tilde{x}(\cdot)$. Then, there exist positive constants $c_1, c_2, c_3, c_4, c_5, c_6$ such that

$$\begin{aligned} |\tilde{x}(t)| &\leq c_1|\Pi\tilde{\xi}(t) + R^\top e(t)| \\ &\leq c_1|\Pi\tilde{\xi}(t)| + c_1|R^\top e(t)| \\ &\leq c_1|\Pi\tilde{\xi}(t)| + c_1|(RR^\top)^{-1}R\tilde{x}(t)| \\ &\leq c_1|\Pi\tilde{\xi}(t)| + c_2\sqrt{V(0, \tilde{x}(t))} \\ &\leq c_3|\tilde{\xi}(t)| + c_4\exp(-\frac{\lambda t}{2})\sqrt{V(0, \tilde{x}(0))} \\ &\leq c_3\exp(\lambda_{\max}(S)t)|\tilde{\xi}(0)| + c_5\exp(-\frac{\lambda t}{2})|e(0)| \\ &\leq c_6\exp(\max\{\lambda_{\max}(S), -\frac{\lambda t}{2}\}t)|\tilde{x}(0)| \end{aligned}$$

where $\lambda_{\max}(S)$ is the largest eigenvalue of S and λ is the local decay rate of V (part 1 of the proof). Finally, exponential stability of the linearization implies local exponential stability of x_* for the closed-loop dynamics.

¹This steps coincide with the ones of Theorem 2.1 of [2]. The same remark applies to the derivations of part III.
