Any discontinuous PWA function is optimal solution to a parametric
linear programming problem

N. A. Nguyen¹, S. Olaru¹, P. Rodriguez-Ayerbe¹

Abstract—Recent studies have investigated the continuous
functions in terms of inverse optimality. The continuity is a
primordial structural property which is exploited in order to
link a given piecewise affine (PWA) function to an optimization
problem. The aim of this work is to deepen the study of the
PWA functions in the inverse optimality context and specifically
deal with the presence of discontinuities. First, it will be shown
that a solution to the inverse optimality problem exists via
a constructive argument. The loss of continuity will have an
implication on the structure of the optimization problem which,
although convex, turns to have a set-valued optimal solution. As
a consequence, the original PWA function will represent an
optimal solution but the uniqueness is lost. From the numerical
point of view, we introduce an algorithm to construct an
optimization problem that admits a given discontinuous PWA
function as an optimal solution. This construction is shown to
rely on convex liftings. A numerical example is considered to
illustrate the proposal.

I. INTRODUCTION

Piecewise affine (PWA) functions have been shown to provide relevance in control design through many studies
e.g. [3], [8], [23], [9], [19], [2], [18], [20], [4]. It is known
that from the practical point of view, PWA control law has
two major limitations in terms of implementation once the
number of regions in the state space becomes large:
- it requires substantial memory to store the state space
  partition and the associated control law gains,
- the point-location problem, determining to which region
  the current state belongs, becomes more expensive.

Due to the above limitations, many studies have been focused on the complexity reduction of PWA control laws e.g.
[11], [10], [12], [6]. Recently, inverse parametric convex
programming problem has received an increasing attention in
control community as a promising approach to realize this
purpose. It is shown in [1] that any continuous nonlinear function is obtainable through a parametric convex program-
ming problem without any hint for the construction of such
an inverse optimality problem. Subsequently, some recent
studies focus on the recovery of continuous PWA functions
defined over polyhedral partitions via the decomposition into
the difference of two convex functions as in [7], or via
convex liftings as in [16], [17]. As emphasized, all these studies focus on the continuous PWA functions, and the
present study aims to compensate the lack of interest for the
discontinuous PWA functions by investigating the inverse
optimality. Note also that due to the continuity of the given
PWA function, the optimal solution to inverse optimality for-
mulation is unique. However, the uniqueness may no longer
be preserved for discontinuous PWA functions. Therefore,
finding an optimization problem, whose optimal solution
is unique and equivalent to the given discontinuous PWA
function, may render this optimization problem nonlinear
(non-convex) at least from the point of view of the cost function.

Motivated from the above discussion, in this paper, we
restrict our effort to show how to construct a convex optimi-
zerization problem that admits the given discontinuous PWA
function as an optimal solution at the price of non-unicy.
Note also that the equivalence between PWA functions is
understood in the sense that the boundary between two neighboring regions sharing the same affine function, can
be adjusted (subdivided). This optimization problem will be
shown to be of parametric linear programming type.

II. PROBLEM FORMULATION

A. Generalities and basic notions

Throughout the paper, \( \mathbb{R}, \mathbb{R}_+, \mathbb{N}, \mathbb{N}_{>0} \) denote the field of
real numbers, the set of non-negative real numbers, the
set of nonnegative integers and the positive integer set,
respectively. The following index set is also defined, for
ease of presentation, with respect to a given
\( N \in \mathbb{N}_{>0} \):
\( \mathcal{I}_N = \{ i \in \mathbb{N}_{>0} \, | \, i \leq N \} \).

Given a finite set \( S := \{ s_1, \ldots, s_L \} \), then \( \text{Card}(S) \) denotes
the cardinal number of \( S \), i.e. \( \text{Card}(S) = L \). \( \text{conv}(A) \)
denotes the convex hull of \( A \). Moreover, if \( R \) is a set of
vectors, by \( \text{cone}(R) \), we denote the cone which has elements of \( R \) as its extreme rays.

A polyhedron is defined as the intersection of a finite
number of halfspaces. A polytope is defined as a bounded
polyhedron. Given a full dimensional polyhedron \( P \subseteq \mathbb{R}^d \),
then \( \mathcal{V}(P) \) denotes the set of its vertices, and \( \mathcal{R}(P) \) denotes
the set of its extreme rays. We use \( k \)-face to denote a face
of dimension \( k \) of \( P \). A 0-face is also called a vertex,
an 1-face is alternatively called an edge, a \((d-1)\)-face
amounts to a facet. Also, \( \mathcal{F}(P) \) denotes the set of facets of
\( P \). Furthermore, by \( \text{int}(S) \), we denote the interior of a full
dimensional set \( S \). If \( S \) is a vector space, and \( S \) is an arbitrary
set, then \( \text{Proj}_S S \) represents the orthogonal projection of
the set \( S \) onto the space \( S \). Also, we use \( \text{dim}(S) \) to denote the
dimension of the affine hull of \( S \).

Given two full dimensional sets \( P_1, P_2 \subseteq \mathbb{R}^d \), then the
Minkowski sum of these two sets, denoted by \( P_1 \oplus P_2 \), is
defined as follows:
\[ P_1 \oplus P_2 = \{ y \in \mathbb{R}^d \mid \exists x_1 \in P_1, x_2 \in P_2, y = x_1 + x_2 \}. \]

The following definitions represent extensions of the ones introduced in [17], [16], [14].

**Definition 1:** A collection of \( N \in \mathbb{N}_{>0} \) full-dimensional polyhedra \( X_i \subset \mathbb{R}^d \) is called a polyhedral partition of a polyhedron \( X \subset \mathbb{R}^d \) if:
1. \( X = \bigcup_{i \in I_N} X_i \),
2. \( \text{int}(X_i) \bigcap \text{int}(X_j) = \emptyset \) with \( i \neq j \), \((i, j) \in I_N^2\).

Also, \((X_i, X_j)\) are called neighbours if \((i, j) \in I_N^2\), \( i \neq j \) and \( \text{dim}(X_i \cap X_j) = d - 1 \).

The notion of cell complex was presented by Grünbaum in [5]. For simplicity, a cell complex can be understood as a polyhedral partition whose facet-tofacet property is fulfilled i.e. any pair of neighboring regions share a common facet.

For ease of presentation, a slight abuse of notation is used in the remainder of this paper: \( X \) denotes simultaneously a polyhedral partition/cell complex of a polyhedron and this polyhedron itself. Its meaning will be clear from the context.

Note that a PWA function \( f_{\text{pwa}}(x) : \mathbb{R}^d \rightarrow \mathbb{R}^n \) defined over a polyhedral partition \( X = \bigcup_{i \in I_N} X_i \subset \mathbb{R}^d \), can be described as follows:

\[ f_{\text{pwa}}(x) = h_i x + g_i \quad \text{for } x \in X_i. \]

With respect to Definition 1, a PWA function is continuous as long as for any neighboring regions \( (X_i, X_j) \),
\[ h_i x + g_i = h_j x + g_j, \quad \forall x \in X_i \cap X_j. \]

Otherwise, if \( f_{\text{pwa}}(x) \) is discontinuous, this discontinuity happens at frontiers between neighboring regions. Thus, such a discontinuous function \( f_{\text{pwa}}(x) \) can be defined as follows:

\[ f_{\text{pwa}}(x) = \begin{cases} h_i x + g_i & \text{for } x \in \text{int}(X_i), \\ h_i x + g_i & \text{or } h_j x + g_j & \text{for } x \in X_i \cap X_j, \end{cases} \]

for every pair of neighboring regions \( (X_i, X_j) \). An alternative way to deal with the discontinuities is to allow multiple values in the codomain \( \mathbb{R}^n \) for a given point \( x \). In this case, we are not dealing anymore with a function but a set-valued map.

**Definition 2:** For a given polyhedral partition \( X = \bigcup_{i \in I_N} X_i \subset \mathbb{R}^d \), a piecewise affine lifting is described by a real-valued function \( z : X \rightarrow \mathbb{R}^d \) with:

\[ z(x) = a_i x + b_i \quad \text{for } x \in X_i, \quad (1) \]

and \( a_i \in \mathbb{R}^d, b_i \in \mathbb{R}, \forall i \in I_N \).

**Definition 3:** Given a polyhedral partition \( X = \bigcup_{i \in I_N} X_i \subset \mathbb{R}^d \), a piecewise affine lifting \( z(x) = a_i x + b_i \forall x \in X_i \), is called convex piecewise affine lifting if the following conditions hold true:

- \( z(x) \) is continuous over \( X \),
- for each \( i \in I_N \), \( z(x) > a_j x + b_j \) for all \( x \in X_i \setminus X_j \) and all \( j \neq i, j \in I_N \).

For ease of presentation, a convex piecewise affine lifting is called, throughout the rest of this paper, convex lifting. It is shown in [21], [15] that a polyhedral partition which admits a convex lifting, is a cell complex. Therefore, a convex lifting is always defined over a cell complex instead of a polyhedral partition.

As discussed above, a given polyhedral partition has to fulfill some conditions for the existence of a convex lifting. A summary of these conditions can be found in [21], [17].

**Definition 4:** A given cell complex \( X = \bigcup_{i \in I_N} X_i \subset \mathbb{R}^d \) has an affinely equivalent polyhedron if there exists a polyhedron \( X \subset \mathbb{R}^{d+1} \) such that for each \( i \in I_N \):

1. \( \exists F_i \in \mathcal{F}(X) \) satisfying: \( \text{Proj}_{\mathbb{R}^d} F_i = X_i \),
2. if \( z(x) = \min z \) s.t. \( x^T z \in X \), then \( \begin{bmatrix} x \\ z(x) \end{bmatrix} \in F_i \) for \( x \in X_i \).

**B. Problem formulation**

As mentioned above, the solutions to inverse parametric linear/quadratic programming problems in [7], [17], [16] are known to only recover continuous PWA functions and to exclude the class of discontinuous PWA functions. This paper concentrates on inverse optimality for the latter class of functions and shows that it can be obtained via convex liftings. This problem can be stated as follows:

**Problem statement:**

Let a polyhedral partition of a polyhedron \( X = \bigcup_{i \in I_N} X_i \subset \mathbb{R}^d \), and a discontinuous PWA function: \( f_{\text{pwa}}(\cdot) : X \rightarrow \mathbb{R}^d \). The goal is to determine \( J(x, z, u), H_x, H_u, H_z, K \) such that:

\[ \begin{align*}
 f_{\text{pwa}}(x) &\in \text{Proj}_{\mathbb{R}^d} \quad \arg \min_{[z \ u]^T} J(x, z, u), \\
 \text{s.t.} \quad H_x x + H_u u + H_z z &\leq K.
\end{align*} \]

The following assumption is necessary for guaranteeing a well-posed problem.

**Assumption 1:** Polyhedral partition \( X \) is convexly liftable. Note that Assumption 1 is not restrictive, in view of Theorem IV.2 in [17]. This theorem is recalled here for completeness.

**Theorem 2.1:** Given a non convexly liftable polyhedral partition \( X = \bigcup_{i \in I_N} X_i \subset \mathbb{R}^d \), there exists at least one subdivision, preserving the internal boundaries of this partition, such that the new cell complex is convexly liftable.

In virtue of this result, if a given polyhedral partition is not convexly liftable, one can subdivide it into a convexly liftable partition such that the internal boundaries are maintained. This new partition is equivalent to the initial one. Therefore, we can focus on convexly liftable partitions throughout the rest of this paper.

Note that this result holds true not only for polytopic partitions (bounded polyhedral partitions) as shown in [17] but also for polyhedral partitions of a polyhedron. The proof is similar to the one presented therein and is omitted for brevity.

**III. CONSTRUCTIVE SOLUTION**

**A. Parametric linear programming**

Constructive solution to inverse optimality problem in this paper is based on convex liftings. It is worth mentioning...
that the algorithm to construct convex liftings, put forward in [17], is not directly applicable for polyhedral partition of polyhedra, since this algorithm is based on the constraints imposed at related vertices. An extension to convex liftings for polyhedral partitions of a polyhedron is referred to in [13]. Based on the above necessary condition, we can state the main result of this paper.

We consider a cell complex of a polyhedron $\mathcal{X} = \bigcup_{i \in \mathcal{I}_N} \mathcal{X}_i \subseteq \mathbb{R}^d$ satisfying Assumption 1 and a possibly discontinuous PWA function $f_{\text{pwa}}(\cdot) : \mathcal{X} \rightarrow \mathbb{R}^d$ defined as follows:

$$f_{\text{pwa}}(x) = \begin{cases} h_i x + g_i & \text{for } x \in \text{int}(\mathcal{X}_i), \\ h_i x + g_i \text{ or } h_j x + g_j & \text{for } x \in \mathcal{X}_i \cap \mathcal{X}_j, \end{cases}$$

where $(\mathcal{X}_i, \mathcal{X}_j)$ are neighbors. We use $\ell(x)$ to denote a convex lifting of this cell complex, i.e.

$$\ell(x) = a_i x + b_i, \quad \text{for } x \in \mathcal{X}_i.$$  

Also, by $f_{\text{pwa}}^{(i)}(x)$, we denote the $i$th component of the function $f_{\text{pwa}}(x)$ at $x$ for $i \in \mathcal{I}_d$. The following sets are defined:

$$V_x = \bigcup_{i \in \mathcal{I}_N} \mathcal{V}(\mathcal{X}_i), \quad R_x = \bigcup_{i \in \mathcal{I}_N} \mathcal{R}(\mathcal{X}_i),$$

$$f_{\text{pwa}}^i(x) = \max_{j \in \mathcal{I}_N; \ell(x) \in \mathcal{X}_j} h_j^i x + g_j^i,$$  

$$f_{\text{pwa}}^{(i)}(x) = \min_{j \in \mathcal{I}_N; \ell(x) \in \mathcal{X}_j} h_j^i x + g_j^i,$$

Note that $f_{\text{pwa}}^i(x)$ is defined as the maximal (minimal) value among the values of the $i$th component of the affine functions composing $f_{\text{pwa}}(x)$ at $x$, defined over the regions which contain $x$.

$$U(x) = \left\{ \begin{bmatrix} u^{(1)}(x) \\ \vdots \\ u^{(d)}(x) \end{bmatrix} : u^{(i)}(x) \in \{ f_{\text{pwa}}^i(x), f_{\text{pwa}}^{(i)}(x) \} \right\},$$

$$V_{[x^T z u^T]^T} = \left\{ \begin{bmatrix} x \\ \ell(x) \\ u(x) \end{bmatrix} : x \in V_x, \ u(x) \in U(x) \right\},$$

$$R_{[x^T z u^T]^T} = \left\{ \begin{bmatrix} r \\ \ell(r) \\ h(r) \end{bmatrix} : r \in R_x, \ h(r) = a_i r \right\},$$

$$\Pi_v = \text{conv}(V_{[x^T z u^T]^T}), \quad \Pi_r = \text{cone}(R_{[x^T z u^T]^T}),$$

$$\Pi = \Pi_v + \Pi_r.$$  

Note that $V_{[x^T z u^T]^T}$ represents the set of extended vertices (extreme rays) of the partition $\mathcal{X}$ in the augmented space. Also from the above construction, if for a given $x \in \mathcal{X}$, we have $f_{\text{pwa}}^{(i)}(x) = f_{\text{pwa}}^i(x)$ for all $i \in \mathcal{I}_d$, then the function $f_{\text{pwa}}(x)$ is continuous at $x$. In this case, $\text{Card}(U(x)) = 1$. The following observation is useful for the next development.

**Proposition 3.1:** For any $x \in \mathcal{X}$ and $U(x)$ defined in (6), $U(x) = \mathcal{V}(\text{conv}(U(x)))$.

**Proof:** Suppose $\mathcal{V}(\text{conv}(U(x))) \subseteq U(x)$, then there exists a point $u_0(x) \in U(x)$ for a given $x \in \mathcal{X}$ such that $u_0(x)$ can be described via a convex combination of the other points $u(x) \in U(x), u(x) \neq u_0(x)$, then

$$u_0(x) = \sum_{u(x) \neq u_0(x)} \alpha(u(x))u(x),$$

$$\alpha(u(x)) \geq 0, \quad \sum_{u(x) \neq u_0(x)} \alpha(u(x)) = 1.$$  

We need to find a contradiction. Indeed, $u_0^{(1)}(x)$ takes value in the discrete set $\{ f_{\text{pwa}}^{(i)}(x), f_{\text{pwa}}^i(x) \}$, and any of these two values cannot be described by a convex combination of the other one if they are different. Thus, $u_0^{(1)}(x) = \sum_{u(x) \neq u_0(x)} \alpha(u(x))u^{(1)}(x)$ holds true if $u^{(1)}(x) = u_0^{(1)}(x)$, meaning:

$$\sum_{u(x) \neq u_0(x)} \alpha(u(x)) = 1,$$

$$\alpha(u(x)) = 0 \text{ for } u^{(1)}(x) \neq u_0^{(1)}(x).$$

The same argument, applied for the other components $u_0^{(i)}(x), i \in \mathcal{I}_d$, leads to:

$$\alpha(u(x)) = 1, \text{ for } u(x) = u_0(x),$$

$$\alpha(u(x)) = 0, \text{ for } u(x) \neq u_0(x).$$

This inclusion is clearly contradictory with (7).

**Proposition 3.2:** $V_{[x^T z u^T]^T} = \mathcal{V}(\Pi_v)$.

**Proof:** Suppose there exists a point of $V_{[x^T z u^T]^T}$, denoted by $[x^T \ell(x) u^T]^T$, which can be described via a convex combination of the other points in this set. Formally, this leads to the following relationship:

$$[x \ell(x) u_0(x)] = \sum_{\ell(v) \neq \ell(x)} \alpha \begin{bmatrix} v \\ \ell(v) \\ u(v) \end{bmatrix},$$

$$[v \ell(v) u(v)] \in V_{[x^T z u^T]^T}$$

where

$$\alpha \begin{bmatrix} v \\ \ell(v) \\ u(v) \end{bmatrix} \geq 0, \quad \sum_{\ell(v) \neq \ell(x)} \alpha \begin{bmatrix} v \\ \ell(v) \\ u(v) \end{bmatrix} = 1.$$  

Due to the fact that any $[x^T \ell(x)]^T, x \in V_x$, cannot be described via a convex combination of the other
[\mathbf{v}^T \ell(v)]^T, v \neq x, v \in V_x, \text{ then relation (8) only holds true for } v = x, \text{ leading to } \alpha \left( \begin{bmatrix} v \\ \ell(v) \\ u(v) \end{bmatrix} \right) = 0 \text{ for } v \neq x. \text{ The remaining coefficients only depend on } u(x), \text{ therefore for ease of presentation, we denote the remaining coefficients by } \alpha(u(x)) \text{ instead of } \alpha \left( \begin{bmatrix} x \\ \ell(x) \\ u(x) \end{bmatrix} \right). \text{ To complete the proof, we need to show that}

\begin{align*}
\alpha(u(x)) &\geq 0, \\
\alpha(u(x)) &\neq u(x), u(x) \in U(x) \\
\alpha(u(x)) &= 0, u(x) \neq u(x), u(x) \in U(x)
\end{align*} 

leads to a contradiction. This end is easily deduced from Proposition 3.1 and the proof is complete. Based on the above inclusions, the main result of the paper is presented below.

**Theorem 3.3:** Any possibly discontinuous PWA function (3) defined over a partition of a polyhedron satisfying Assumption 1, is the image via the orthogonal projection onto \( R^d_x \) of an optimal solution to the following optimization problem:

\[
\begin{align*}
\min_{[z \ u]^T} z \quad \text{s.t.} \quad & \begin{bmatrix} x^T & z^T & u^T \end{bmatrix}^T \in \Pi, \\
\end{align*}
\]

where \( \Pi \) is defined as in (6).

**Proof:** Given a point \( x \in X_i \) in the cell complex \( X \), due to the Minkowski-Weyl theorem (see Corollary 7.1b in [22]), \( x \) can be written as a convex combination as follows:

\[
x = \sum_{v \in V(X \cap i)} \alpha(v)v + \sum_{r \in R(X \cap i)} \beta(r)r,
\]

where \( \alpha(v), \beta(r) \geq 0; \sum_{v \in V(X \cap i)} \alpha(v) = 1 \). Due to Assumption 1, let \( \ell(x) \) denote a convex lifting of the cell complex \( X \), i.e., \( \ell(x) = \sum_{v \in V(X \cap i)} \alpha(v)x + b_i \) for \( x \in X_i \). For an \( x \in X_i \), it follows that:

\[
\ell(x) = a_x + b_i = \sum_{v \in V(X \cap i)} \alpha(v)(a_xv + b_i) + \sum_{r \in R(X \cap i)} \beta(r)a_{r}r.
\]

Thus, if we define the following sets:

\[
V_{[x^T z]^T} = \left\{ \begin{bmatrix} x \\ \ell(x) \end{bmatrix} \mid x \in X_i \right\},
\]

\[
R_{[x^T z]^T} = \left\{ \begin{bmatrix} r \\ \ell(r) \end{bmatrix} \mid r \in R_x, \ell(r) = a_{r}r \text{ if } r \in R(X \cap i) \right\},
\]

then \( \Pi_{[x^T z]^T} = \text{conv}(V_{[x^T z]^T}) \oplus \text{cone}(R_{[x^T z]^T}) \) is an affinely equivalent polyhedron of the cell complex \( X \).

Following the definition of an affinely equivalent polyhedron, for a region \( X_i \) in the given cell complex \( X \), there exists a lower facet of \( \Pi_{[x^T z]^T} \), denoted by \( F_{[x^T z]^T} \) such that \( \text{Proj}_{R^d_x} F_{[x^T z]^T} = \hat{X}_i \) and the optimal solution to the following optimization problem:

\[
\min_{[z \ u]^T} z \quad \text{s.t.} \quad [x^T z^T u^T]^T \in \Pi_{[x^T z]^T},
\]

falls in \( F_{[x^T z]^T} \) for \( x \in X_i \). Note however that, due to the construction in (6), every \( d_x \)-face, denoted by \( F^\# \) and defined as follows:

\[
F^\# = F^RB_{1} \oplus F^B_2,
F^B_1 = \text{conv} \left\{ \begin{bmatrix} v^T & \ell(v) & u^T(v) \end{bmatrix}^T \mid v \in V(X \cap i) \right\},
F^B_2 = \text{cone} \left\{ \begin{bmatrix} r^T & a_{r}r & (h_{i}r)^T \end{bmatrix}^T \mid r \in R(X \cap i) \right\},
\]

(11)

satisfies: \( \text{Proj}_{R^d_x} F^\# = F_{[x^T z]^T} \). Also, consider a point \( x \in X_i \), optimizer of the optimization problem (10) at \( x \), locates on such a \( d_x \)-face \( F^\# \). Due to this non-uniqueness, we can choose the following \( d_x \)-face, denoted by \( F_{i} \), defined as in (11) with \( u(v) = h_{i}v + g_i \) for \( v \in X \). Then, for any \( x \in X_i \), the optimizer, located on \( F_{i} \), satisfies:

\[
\begin{bmatrix} x \\ z^*(x) \end{bmatrix} = \sum_{v \in V(X \cap i)} \alpha(v) \begin{bmatrix} v \\ \ell(v) \end{bmatrix} + \sum_{r \in R(X \cap i)} \beta(r) \begin{bmatrix} r \\ a_{r}r \end{bmatrix},
\]

meaning \( u^*(x) = h_{i}x + g_i = f_{pwa}(x) \).

**Remark 1:** Note that one can easily fix a large enough box in \( R^d_x \) to bound every \( U(x), \forall x \in V_x \). Such a constraint can avoid the computation of \( U(x) \) at each vertex of the cell complex \( X \). However, such a choice ignores the structure of the given PWA function and cannot exploit its continuity property whenever this exists.

Algorithm 1 summarizes the construction presented above.

**Algorithm 1:** Constructive solution to inverse optimality problem for discontinuous PWA functions

**Input:** A discontinuous PWA function (3), i.e., \( f_{pwa}(x) \) defined over convexly liftable cell complex \( X \).

**Output:** \( H_x, H_u, H_z, K, J(x, z, u) \).

1. Compute a convex lifting \( \ell(x) \) of the cell complex \( X \).
2. Construct a constraint set \( \Pi \) as in (6).
3. Define \( J(x, z, u) = z \).
4. Solve the following parametric linear programming problem:

\[
\begin{align*}
\min_{[z \ u]^T} z \quad \text{s.t.} \quad & [x^T z^T u^T]^T \in \Pi,
\end{align*}
\]

**B. Connections to parametric quadratic programming**

Similar to the above construction, a simple extension from parametric linear programming to a parametric quadratic programming problem is introduced below.

**Theorem 3.4:** Given a possibly discontinuous PWA function (3) defined over a partition of a polyhedron satisfying Assumption 1, one of its associated convex lifting (4), let \( \sigma(x) \) be a function \( \sigma(x) \leq \ell(x) \) for \( x \in X \). The given PWA function (3) is the image via the orthogonal projection onto \( R^d_x \) of an optimal solution to the following parametric quadratic programming problem:

\[
\begin{align*}
\min_{[z \ u]^T} (z - \sigma(x))^2 \quad \text{s.t.} \quad & [x^T z^T u^T]^T \in \Pi,
\end{align*}
\]

(12)
where Π is defined as in (6).

Proof: Due to the assumption that σ(x) ≤ ℓ(x) for
x ∈ X, the optimization problem (12) amounts to the
minimization of z subject to the same constraints. Therefore,
by Theorem 3.3, f_pwa(x) is a sub-component of an optimal
solution to problem (12). The proof is complete.

To conclude the analysis of piecewise affine functions and
their inverse optimality, the following theorem presents the
main message of the paper.

Theorem 3.5: Any possibly discontinuous PWA function,
defined over a polyhedral partition of a polyhedron, can be
equivalently obtained as a selection among the optimal solu-
tions of a parametric linear/quadratic programming problem.

Proof: Let f_pwa(x) denote a given PWA function,
defined over a polyhedral partition X. If the partition X is
convexly liftable, Theorems 3.3, 3.4 show in a constructive
manner parametric linear/quadratic programming problems
for which f_pwa(x) is a sub-component of an optimal
solution.

Otherwise, if X is not convexly liftable, as per Theorem
2.1, one can subdivide X into a convexly liftable cell com-
xplex such that the internal boundaries are maintained. Ac-
cording to this new cell complex, f_pwa(x) is also subdivided
into an equivalent PWA function, say f̃pwa(x). Note also that
this equivalent function f̃pwa(x) is defined over a convexly
liftable partition. Again, according to Theorems 3.3, 3.4,
f̃pwa(x) can be obtained via parametric linear/quadratic
programming problems.

IV. NUMERICAL EXAMPLE

Consider a simple discontinuous PWA function f_pwa(x),
deﬁned over a partition in R as follows:

\[
f_{pwa}(x) = \begin{cases}
0.8116x + 0.5328 & \text{for } -0.4 \leq x < -0.3 \\
0.3507x + 0.9390 & \text{for } -0.3 \leq x < -0.2 \\
0.8759x + 0.5022 & \text{for } -0.2 \leq x < -0.1 \\
0.6225x + 0.5870 & \text{for } -0.1 \leq x < 0 \\
0.2077x + 0.3012 & \text{for } 0 \leq x < 0.1 \\
0.4709x + 0.2305 & \text{for } 0.1 \leq x < 0.2 \\
0.8443x + 0.1948 & \text{for } 0.2 \leq x < 0.3 \\
0.2259x + 0.1707 & \text{for } 0.3 \leq x < 0.4 \\
\end{cases}
\]

One can easily check the discontinuity of this function via its
values at the vertices of the regions in the parameter space
partition (see Fig.1). A convex lifting of this partition denoted
by ℓ(x), is presented below:

\[
ℓ(x) = \begin{cases}
-3.5x + 0.4 & \text{for } -0.4 \leq x \leq -0.3 \\
-2.5x + 0.7 & \text{for } -0.3 \leq x \leq -0.2 \\
-1.5x + 0.9 & \text{for } -0.2 \leq x \leq -0.1 \\
-0.5x + 1 & \text{for } -0.1 \leq x \leq 0 \\
0.5x + 1 & \text{for } 0 \leq x \leq 0.1 \\
1.5x + 0.9 & \text{for } 0.1 \leq x \leq 0.2 \\
2.5x + 0.7 & \text{for } 0.2 \leq x \leq 0.3 \\
3.5x + 0.4 & \text{for } 0.3 \leq x \leq 0.4 \\
\end{cases}
\]

Also, this convex lifting is shown in Fig.2. Following the
approach presented previously, an optimization problem that
admits the given PWA function as an optimal solution, is
presented in (13).

The given discontinuous PWA function is presented in
Fig.1 wherein the line along the horizontal axis describes the
parameter space x and the multicolored lines above describe
the given PWA function. Also, in the extended space of
parameter x, the original function f_pwa(x), lifting ℓ(x), the
green lines in Fig.3 represent the given PWA function. The
shaded pink polytope represents a set of constraints Π in
the inverse optimization problem. Note also that the solid
pink lines describe an optimal solution to this optimization
problem. Moreover, the images of these lines onto the space
of (x, f_pwa(x)) coincide with the given PWA function. It
is also worth emphasizing that for each segment of state
space partition, the set of optimal solutions to the above
optimization problem represents a facet of the pink polytope
Π, which is orthogonal to the space (x, z). As illustrated in
Fig.4, the pink facets represent the set of optimal solutions
to the optimization problem (13).

\[

V. CONCLUSIONS

This paper presents an inverse optimality result for the
class of discontinuous PWA functions. The solution is based
on convex liftings and leads to a linear programming type
of solution. It is also emphasized that optimal solution to
such an optimization problem is no longer unique but a
set of solutions containing the given discontinuous PWA
function. A numerical example is considered to illustrate
these results. The result is mainly theoretical and sheds light
on the difficulties of discontinuous PWA control law design via convex optimization. Basically, it shows that convex lifting can emulate the polyhedral partition and translate to the constraint set of an optimization problem. However, in order to recover the unicity of the optimizer, the cost function needs to embed the discontinuity via a nonlinear function.
