HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Perturbed-Law based sensitivity Indices for sensitivity analysis in structural reliability

ROMAN, SUEUR[†]; NICOLAS, BOUSQUET[†]; BERTRAND, IOOSS[†];
JULIEN, BECT[‡]

For sensitivity analysis of model outputs, the most popular methods are those based on the variance decomposition of the output, such as the Sobol' indices, as they allow defining easy-to-interpret indices measuring the contribution of each input variable to the overall output dispersion. However, these indices are not adapted to the analysis of the impact of inputs on quantities characterizing extreme events, such as a failure probability, a quantile or a failure domain (Lemaître et al., 2015). We denote $g(\cdot)$ the studied model, $\mathbf{X} = (X_1, \dots, X_d) \in \mathbb{X}$ the random vector of the d independant input variables and $Y = g(\mathbf{X})$ the model output. \mathbf{X} follows a joint probability density function $f(\mathbf{x})$. We focus on a typical problem in structural reliability (Morio and Balesdent, 2015), which is the analysis of the failure probability (the failure event arrives with the event $g(\mathbf{x}) < 0$):

$$p = \int_{\mathbb{X}} \mathbf{1}_{\{g(\mathbf{x}) < 0\}} f(\mathbf{x}) d\mathbf{x}.$$

PERTURBED-LAW BASED SENSITIVITY INDICES

Based on the perturbation of each marginal input density, a new type of sensitivity indices has been recently developed (Lemaître et al., 2015). An input X_i , with marginal density f_i , is replaced by the perturbed variable $X_{i\delta}$. $X_{i\delta}$ follows the density $f_{i\delta}$, based on the initial f_i perturbed of a δ quantity. This allows defining the following perturbed probability $p_{i\delta}$:

$$p_{i\delta} = \int_{\mathbb{X}} \mathbf{1}_{\{g(\mathbf{x}) < 0\}} \frac{f_{i\delta}(x_i)}{f_i(x_i)} f(\mathbf{x}) d\mathbf{x}.$$

From this quantity, we define the Perturbed-Law based Indices (PLI) in the following way:

$$S_{i\delta} = \left[\frac{p_{i\delta}}{p} - 1 \right] \mathbf{1}_{\{p_{i\delta} > p\}} + \left[\frac{p}{p_{i\delta}} - 1 \right] \mathbf{1}_{\{p_{i\delta} \leq p\}}. \quad (1)$$

The PLI measures have some expected properties, such as being equal to 0 when the failure probability is not changed by the perturbation, or taking a sign that indicates the direction of change of the probability with the δ perturbation. $f_{i\delta}$ is obtained by minimizing the Kullback-Leibler divergence KL between $f_{i\delta}$ and f_i for a given shift δ of a statistical characteristic (for example the mean, the variance, a quantile, ...) of the distribution of X_i :

$$KL(f_{i,\delta}, f_i) = \int_{-\infty}^{+\infty} f_{i,\delta}(x_i) \log \frac{f_{i,\delta}(x_i)}{f_i(x_i)} dx_i.$$

Easy minimization of KL provides explicit (analytical) solutions of $f_{i\delta}$ for a large range of perturbed parameters of f_i (e.g. mean, variance, ...) on classical pdf (e.g. Gaussian). In other cases, a numerical optimization procedure is required (Lemaître et al., 2015).

MONTE-CARLO ESTIMATION OF THE PLI MEASURES

An analytical calculation of the probabilities p and $p_{i\delta}$ is not possible in practice, and a Monte-Carlo sample $(\mathbf{x}^{(1)}, \mathbf{x}^{(2)}, \dots, \mathbf{x}^{(N)})$ is used. Thus, the estimations are respectively:

$$\hat{p}_N = \frac{1}{N} \sum_{n=1}^N \mathbf{1}_{g(\mathbf{x}^{(n)}) \leq 0} \quad \text{and} \quad \hat{p}_{i\delta, N} = \frac{1}{N} \sum_{n=1}^N \mathbf{1}_{\{g(\mathbf{x}^{(n)}) \leq 0\}} \frac{f_{i\delta}(x_i^n)}{f_i(x_i^n)}.$$

In practice, the estimation of PLI might require a large-size sample if the failure probability is very low (for instance 10^{-6} or less). This could reveal impractical if the code g is costly.

To improve the estimation of p and $p_{i\delta}$, the importance sampling or subset simulation methods could be used but they often remain too costly in practice (Morio and Balesdent, 2015). We propose here to use a metamodel-based approach which has shown a noticeable efficiency for Sobol' indices (Le Gratiet et al., 2016). In particular, the Gaussian process metamodel allows to control the error on the sensitivity estimates due to the metamodel approximation.

BAYESIAN IMPORTANCE SAMPLING

The so-called Bayesian Importance Sampling (BIS) consists in two steps :

- 1) A Gaussian process model \tilde{g} of the code is built using a budget of $N_0 < N$ computer experiments. This allows to define a relevant importance density at the following step;
- 2) p and $p_{i\delta}$ are estimated with a $N_1 = N - N_0$ importance sampling scheme (Bect et al., 2015).

The Bayesian optimal importance density $f_{IS}^*(\mathbf{x})$ is proportional to $f(\mathbf{x})\sqrt{\mathbb{P}_{N_0}^{\tilde{g}}[g(\mathbf{x}) < 0]}$. If \hat{Z} is an estimator of $Z = \int_{\mathbb{X}} f(\mathbf{x})\sqrt{\mathbb{P}_{N_0}^{\tilde{g}}[g(\mathbf{x}) < 0]}d\mathbf{x}$, the estimate of p is

$$\hat{p}_{i\delta, N_0, N_1}^{BIS} = \frac{\hat{Z}}{N_1} \sum_{n=1}^{N_1} \frac{\mathbf{1}_{\{\mathbb{E}_{N_0}^{\tilde{g}}[\tilde{g}(\mathbf{x}^n)] < 0\}}}{\sqrt{\mathbb{P}_{N_0}^{\tilde{g}}[g(\mathbf{x}^n) < 0]}} \frac{f_{i\delta}(x_i^n)}{f_i(x_i^n)}.$$

PERSPECTIVES: PLI FOR SENSITIVITY ANALYSIS OVER A QUANTILE

In safety studies, a large quantile value is often preferred to a failure probability computation. PLI measures can be applied to an output quantile $q_\alpha(Y) = \inf\{y \text{ s.t. } F(y) \geq \alpha\}$ with F the distribution function of Y . This requires to combine quantile estimation and importance sampling. A naive approach for the estimation of quantiles could consist in replacing F by its empirical estimator in the latest formula. By re-ordering the $y^n = g(\mathbf{x}^n)$ we could define $k_{\alpha, i\delta}$ by

$$k_{\alpha, i\delta} = \min \left\{ k \text{ s.t. } \left[\frac{\sum_{n=1}^k f_{i\delta}(x_i^{(n)})}{f_i(x_i^{(n)})} \right] / \left[\frac{\sum_{n=1}^N f_{i\delta}(x_i^{(n)})}{f_i(x_i^{(n)})} \right] \geq \alpha \right\},$$

where each (n) denotes the re-ordered index of y^n in our sample. A straightforward estimator of $q_\alpha(Y)$ is given by $\hat{q}_\alpha(Y) = y^{k_\alpha}$. However, this estimator is unlikely to show good consistency properties, since it is built on a non-continuous quantile function obtained by inverting the empirical cumulative distribution function of Y . A more promising approach would be to use a quantile-regression framework (Egloff and Leippold, 2010). We notice that $q_\alpha(Y)$ can be written as $\operatorname{argmin}_r \mathbb{E}_X[\rho_\alpha(g(X) - r)]$, where ρ_α denotes the check-function $\rho_\alpha(u) = u(\alpha - \mathbf{1}_{\{u < 0\}})$ (see Fort et al., 2016). This suggests the following estimator:

$$\hat{q}_{\alpha, i\delta}(Y) = \operatorname{argmin}_r \sum_{n=1}^N \rho_\alpha(g(\mathbf{x}^n) - r) \frac{f_{i\delta}(x_i^n)}{f_i(x_i^n)}.$$

Replacing p and $p_{i\delta}$ in (1) respectively by \hat{q}_α and $\hat{q}_{\alpha, i\delta}$ provides the wanted PLI over a quantile.
