HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Multiway Generalized Canonical Correlation Analysis

Keywords: Multiway data analysis, PLS, Canonical Correlation Analysis, RGCCA.

Regularized generalized canonical correlation analysis (RGCCA) is a general framework that encompasses several important multivariate analysis methods. In this paper, we extend RGCCA to the case where data blocks have a tensor structure.

1 Introduction

We consider \(L\) data matrices \(X_1, \ldots, X_l, \ldots, X_L\). Each \(l \times j_l\) data matrix \(X_l\) is called a block and represents a set of \(j_l\) variables observed on \(l\) individuals. The number and the nature of the variables may differ from one block to another, but the individuals must be the same across blocks. We assume that all variables are centered. The objective of RGCCA is to find block components \(y_l = X_l w_l, l = 1, \ldots, L\) (where the block-weight vector \(w_l\) is a column-vector with \(j_l\) elements) summarizing the relevant information between and within the blocks. The second generation RGCCA, detailed in [1], subsumes fifty years of multiblock component methods and is defined as the following optimization problem:

\[
\max_{w_1, \ldots,w_L} \sum_{k,l=1}^L c_{kl} g(I^{-1}w_k^T X_k^T X_l w_l) \quad \text{s.t.} \quad w_l^T M_l w_l = 1, \quad l = 1, \ldots, L \tag{1}
\]

With \(g\) a convex function, \(M_l\) a positive definite matrix and \(C = (c_{kl})\) a symmetric \(L \times L\) matrix of nonnegative elements describing the network of connections between blocks that the user wants to take into account. Usually, \(c_{kl} = 1\) for two connected blocks and 0 otherwise.

2 Multiway Generalized Canonical Correlation Analysis

In this paper, we adopt the standardized notations and terminology proposed by [2] for multiway data analysis. Let us consider \(L\) tensors \(\mathbf{X}_1, \ldots, \mathbf{X}_l, \ldots, \mathbf{X}_L\). Each tensor \(\mathbf{X}_l\) is of dimension \(l \times j_l \times K_l\) and represents a set of \(j_l\) variables observed over \(K_l\) modalities on \(l\) individuals. The number of frontal and lateral slices and the nature of the variables can differ from one tensor to another, but the individuals must be the same across tensors. Let \(\mathbf{X}_l\) be the matricized version of \(\mathbf{X}_l\). Each matrix \(\mathbf{X}_l\) is of dimension \(l \times j_l K_l\) and represents all the frontal slices of \(\mathbf{X}_l\) next to each other. The major drawback of the optimization problem (1) applied to matricized three-way data \(\mathbf{X}_1, \ldots, \mathbf{X}_L\) is that the data structure is not preserved and leads potentially (i) to very large \(j_l K_l\) block-weight vector to estimate and (ii) to an estimation procedure that ignores the original three-way structure of the data. These aspects can yield a lack of relevant interpretations and additional structural constraints are required. From that perspective, we propose Multiway Generalized Canonical Correlation Analysis (MGCCA) that specifically address the peculiar three-way structure of the data within the RGCCA.
optimization process. The MGCCA optimization problem is defined as the following optimization problem:

$$\max_{w_1, ... , w_L} \sum_{k=1}^{L} c_{kl} g(I^{-1}w_k^T X_k^T X_k w_l) \quad \text{s.t.} \quad w_i^T M_i w_l = 1 \quad \text{and} \quad w_l = w_l^K \otimes w_l^J, \quad l = 1, ..., L \quad \quad (2)$$

The weight vectors $w_l, l = 1, ..., L$ are modeled as the Kronecker product between a weight vector $w_l^K$ associated with the $K_l$ frontal slices and a weight vector $w_l^J$ associated with the $J_l$ lateral slices: $w_l = w_l^K \otimes w_l^J, l = 1, ..., L$. This structural constraints yield a more parsimonious model ($J_l + K_l$ instead of $J_l \times K_l$ parameters to estimate), and allows to separately study the effects of the variables and the modalities. These Kronecker constraints are usual in the multi-way literature ([3], [4] and [5]). A fast algorithm that converges to a stationary point of (2) is implemented (proof of convergence published soon) and is available as part of the RGCCA package [6].

3 Analysis of Raman Spectroscopy data

This study aims at analyzing the efficiency of a moisturizer thanks to Raman spectroscopy. For this, on $l = 13$ volunteers, a Raman spectroscopy was performed on both of their arms over $K = 7$ different depths each of which lead to $J = 751$ wavelengths. However, only one of their arms had received the moisturizer. Thus, one arm plays the role of the control, the other one of the test. In addition, the acquisition was repeated at $L = 5$ time points. The resulting dataset is characterized by 5 three-way tensors of dimension $26 \times 751 \times 7$. In this context, MGCCA will provide time points, wavelengths and depths that help to discriminate between treated and non-treated arms. Figure 1.c shows the $w_l^K$ and 1.d the $w_l^K$ coefficients obtain for $l = 1, ..., 5$. It appears that at each time point, wavelengths that discriminate the most between treated and non-treated arms are the ones associated to the absorption band of water.

![Figure 1](image)

Figure 1 – For an individual, intensity of absorption depending on the wavelength and the depth of the skin, for a non-treated (a) and a treated (b) arm. (c) shows the $w_l^K$ coefficients (associated to the wavelengths) and (d) shows the $w_l^K$ coefficients (associated to the depths P1 to P7) for $l = 1, ..., 5$ (associated to the time).

4 Conclusion

Work in progress includes to incorporate within the optimization problem (2) specific penalties on the weight vectors $w_l^K$ and $w_l^K$.
