ABSTRACT
In modern array processing or spectral analysis, mostly two different signal models are considered: the conditional signal model (CSM) and the unconditional signal model. The discussed signal models are Gaussian and the parameters are connected either with the expectation value in the conditional case or with the covariance matrix in the unconditional one. We focus on the CSM where several independent observations of the same individual signals are available, which are allowed to perform a Gaussian random walk between observations. In the proposed generalized CSM, the parameters are connected with both the expectation value and the covariance matrix, which is a significant change in comparison with the usual CSM. Even if the batch form of the associated generalized conditional maximum likelihood estimators (GCMLEs) can be easily exhibited, it becomes uncomputable as the number of observations increases. As a main contribution, we introduce a recursive form of GCMLEs which allows to explore, by Monte-Carlo simulations, their asymptotic performance in terms of mean-squared error. We exhibit non consistent GCMLEs when the number of observations tends to infinity, which highlights the consequence of combining (even slightly) dependent observations.

Index Terms— Deterministic parameter estimation, conditional maximum likelihood estimators, mean-squared error, consistency

1. INTRODUCTION
In many practical problems of interest (radar, sonar, communication, ...) dealing with deterministic parameters estimation, the observations consists of a complex circular vector [1][2]. In this instance, one of the most studied estimation problem is that of identifying the components of observations (yk) formed from a linear superposition of P individual signals (xk) to noisy data (vk) [3][4][5][6]:

\[ y_k = H_k(\theta)x_k + v_k, y_1, v_1 \in M_C(\mathbb{N}_1, 1) \]

The mixing matrix depends on an unknown deterministic parameter vector \( \theta \). This problem has received considerable attention during the last fifty years, both for time series analysis [5] and array processing [6]. In the first case, one usually has to estimate the frequencies of complex sine waves from a single experiment data. In the second case, one looks for the directions of arrival (or spatial frequencies) of multiple plane waves impinging on a narrow-band array of sensors using multiple snapshots. Theses two problems have been merged into the framework of modern array processing [6][7] where mostly two different signal models are considered: the conditional signal model (CSM) and the unconditional signal model [4][8][9]. The discussed signal models are Gaussian and the angular/frequency dependency is given by parameters which are connected with the expectation value in the conditional case and with the covariance matrix in the unconditional one. In this paper, we focus on the CSM where the independent observations of \( x_k \) are available:

\[ y_l = H_l(\theta) x_l + v_l, y_1, v_l \in M_C(\mathbb{N}_1, 1), 1 \leq l \leq k \]

In the standard CSM, \( v_l \sim \mathcal{CN}(0, \sigma^2_l I) \) and the individual signals \( x_l \) are assumed to remain perfectly constant during the \( k \) observations. If one concatenates the observation vectors \( y_k \) on a horizon of \( k \) observations from the first observation, i.e. \( \bar{y}_k = (y_1^T, \ldots, y_k^T) \), then one obtains the following global CSM:

\[ \bar{y}_k = H_k(\theta)x_1 + \bar{v}_k, \bar{y}_k \sim \mathcal{CN}(\bar{H}_k(\theta)x_1, \sigma^2_k I) \]

where \( \bar{y}_k, \bar{v}_k \in M_C(\mathbb{N}_k, 1), \bar{H}_k(\theta) \in M_C(\mathbb{N}_k, P) \) and the Gaussian fluctuation noise sequence \( \{v_l\}_{l=1}^k \) is white and uncorrelated with the Gaussian measurement noise sequence \( \{v_l\}_{l=1}^k \). The Gaussian random walk (2a) of the individual signals \( x_l \) allows to define a more general class of CSM. The most noteworthy point introduced by the proposed generalized CSM, is that the parameters \( \theta \) are now connected with both the expectation value and the covariance matrix, which is a significant change in comparison with the usual CSM. Indeed, since:

\[ x_l = \mathbf{B}_{11} x_1 + \sum_{q=1}^{l-1} \mathbf{B}_{1,q+1} w_q, \mathbf{B}_{i,q} = \begin{bmatrix} 1 & l = q \ 0 & l < q \end{bmatrix} \]

an equivalent form of (2b) is:

\[ y_l = \mathbf{A}_l(\theta) x_1 + n_l, \quad \mathbf{A}_l(\theta) = \mathbf{H}_l(\theta) \mathbf{B}_{11}, \quad n_l = v_l + H_l(\theta) G_l \bar{w}_{l-1}, \quad 2 \leq l \leq k \]

where \( G_l \bar{w}_{l-1} = \sum_{q=1}^{l-1} \mathbf{B}_{1,q+1} w_q, \ G_l \in M_C(P, (l-1) P) \), leading to:

\[ \bar{y}_k = \bar{A}_k(\theta)x_1 + \bar{n}_k, \quad \bar{y}_k \sim \mathcal{CN}(\bar{A}_k(\theta)x_1, C_{\bar{P}_k}(\theta)) \]
As shown in Section 2, in the simplest case where the set of unknown parameters is restricted to $x_1$ and $\theta$, the MLEs of $\theta$ based on $y_k$ (3b), so-called in the following the generalized CMLE (GCMLE) of $\theta$, is the solution of the maximization of a non-linear multidimensional optimization problem involving the computation of $C_{\hat{\theta}}(\theta)$ and $|C_{\hat{\theta}}(\theta)|$, where $C_{\hat{\theta}}(\theta)$ is not block diagonal (except if $C_{w_l} = 0, 1 \leq l \leq k-1$). Therefore, at first sight, the computation of the GCMLE of $\theta$ seems to become computationally prohibitive as the number of observations $k$ increases, which would limit the interest of the proposed model. Fortunately, the observation model of interest (2a-2b) belongs to the general class of linear discrete state-space (LDSS) models [10][11] represented with the state (2a) and measurement (2b) equations. By exploiting some new results on linear minimum variance distortionless response filters (LMVDRFs) for LDSS models [12], we show that the GCMLEs of $x_1$ and $\theta$ can be recursively computed from observation to observation without the need to compute at each observation $C_{\hat{\theta}}(\theta)$ nor $|C_{\hat{\theta}}(\theta)|$. The recursive form of the GCMLE allows to explore, by Monte-Carlo simulations, its asymptotic performance in terms of mean-squared error (MSE). For instance, the example given in Section 4 exemplifies the non negligible impact of an amplitude fluctuation which introduces a lower limit in the achievable MSE of GCMLEs.

From a practical point of view, the existence of this lower limit shows that, when signal sources fluctuate, there exists an optimal number of observations that can be combined coherently in order to estimate their amplitudes and other unknown associated parameters with the minimum (or almost minimum) achievable MSE.

From a theoretical point of view, we exhibit non consistent MLEs when the number of observations tends to infinity, which highlights the consequence of combining (even slightly) dependent observations. Last but not least, the recursive form of GCMLEs is also a key feature for real-world applications [10][11] where the observations become available sequentially and, immediately upon receipt of new observations, it is desirable to determine new estimates based upon all previous observations (including the current ones).

### 2. Batch Form of GCMLEs

For the sake of simplicity, we assume that $\sigma_x^2, \{F_i\}_{i=1}^{k-1}, \{C_{w_i}\}_{i=1}^{k-1}$ are known. Thus the set of unknown parameters is restricted to $x_1$ and $\theta$. Since $y_k \sim C_N(\widehat{x}_k(\theta), x_1, C_{\hat{x}_k}(\theta))$ (3a-3b), the log likelihood function is up to a constant value, defined as [5][6][7]:

$$L(\widehat{x}_k; \theta, x_1) = -\ln |C_{\hat{x}_k}(\theta)| - (y_k - \widehat{x}_k(\theta)x_1)^H C_{\hat{x}_k}(\theta)^{-1} (y_k - \widehat{x}_k(\theta)x_1),$$

leading to the following definition of the GCMLEs of $x_1$ and $\theta$:

$$\widehat{x}_{1|k}(\theta) = \arg \max_{x_1,\theta} \{L(\widehat{x}_k; \theta, x_1)\},$$

It is then well known [5][6][7] that $\widehat{x}_{1|k} = x_{1|k}(\theta)$, where:

$$x_{1|k}(\theta) = \left(\widehat{x}_k(\theta) C_{\hat{x}_k}(\theta)^{-1} \widehat{x}_k(\theta)^H \right) C_{\hat{x}_k}(\theta)^{-1} \widehat{x}_k(\theta) x_1,$$

$$\widehat{\theta}_k = \arg \max_{\theta} \{L(\widehat{x}_k; \theta, x_{1|k}(\theta))\},$$

or equivalently:

$$\widehat{\theta}_k = \arg \max_{\theta} \{J_k(\theta) - J_k(\theta)\},$$

$$J_k(\theta) = \|C_{\hat{x}_k}(\theta)^{-1} \widehat{x}_k(\theta)\|^2, J_k(\theta) = \ln |C_{\hat{x}_k}(\theta)|.$$
3.2. Recursive form of $x_{1|k}$ and $I_k$

By noticing that:

$$\Pi_{\mathbf{x}_k}^{-1}\mathbf{y}_k = \mathbf{A}_k^{-1} \left( \mathbf{A}_k^H \mathbf{C}_{\pi_k}^{-1} \mathbf{A}_k \right)^{-1} \mathbf{A}_k^H \mathbf{C}_{\pi_k}^{-1} \mathbf{y}_k = \mathbf{A}_k x_{1|k},$$

$I_k$ can be rewritten as:

$$I_k = x_{1|k}^H \mathbf{P}_{1|k}^{-1} x_{1|k}, \quad \mathbf{P}_{1|k} = \left( \mathbf{A}_k^H \mathbf{C}_{\pi_k}^{-1} \mathbf{A}_k \right)^{-1}. \quad (13)$$

In order to exhibit a recursive formulation of $x_{1|k}$ (6) and $I_k$ (8b), firstly, one builds from (2a-b) an auxiliary LDSS model consisting of the same observations associated with an augmented state for $k \geq 2$:

$$l = 1:\quad y_1 = H_1 x_1 + v_1,$n
$$l = 2:\quad y_2 = H_2 x_2 + v_2,$n
$$l \geq 3:\quad y_l = H_l x_l + v_l,$n

that is, in short:

$$x_1' = x_1, \quad y_1 = H_1 x_1 + v_1,$n
$$x_2' = x_2, \quad y_2 = H_2 x_2 + v_2,$n
$$x_l' = x_l, \quad y_l = H_l x_l + v_l,$n

where $H_1 = H_2 = H_1$, and (3a) becomes:

$$y_1 = A_1 x_1 + n_1', \quad A_1' = H_1 B_1', \quad n_1' = n_1 + H_1 G \mathbf{w}_{l-1}.$$n

By definition:

$$B_1' = F_1' \cdots F_{l-1}' F_1', \quad A_1' = H_1 B_1', \quad n_1' = n_1 + H_1 G \mathbf{w}_{l-1}.$$n

Moreover since $G' \mathbf{w}_{l-1} = \sum_{q=1}^{l-1} B_{q+1}' w_q = \left( G' \mathbf{w}_{l-1} \right)$, then:

$$n_1' = n_1 + H_1 G \mathbf{w}_{l-1} = n_1 + H_1 G \mathbf{w}_{l-1},$$n

Secondly, since $H_1$ and $C_{v_1}$ are full rank, if we consider the LDSS model (14), the LMDVF of $x_{1|k}$ exists and is defined by (11a):

$$\mathbf{W}_k^b = \arg \min_{\mathbf{W}_k} \{ \mathbf{P}_{k|k} (\mathbf{W}_k) \} \quad \text{s.t.} \quad \mathbf{W}_k^b \mathbf{A}_k = B_{k|1}, \quad (15a)$$

where $\mathbf{P}_{k|k} (\mathbf{W}_k) = E \left[ \left( \mathbf{W}_k^b \mathbf{y}_k - x_k' \right) \left( \mathbf{W}_k^b \mathbf{y}_k - x_k' \right)^H \right]$, which is equivalent to (11b):

$$\mathbf{W}_k^b = \arg \min_{\mathbf{W}_k} \{ E \left[ r_k F_k^H \right] \} \quad \text{s.t.} \quad \mathbf{W}_k^b \mathbf{A}_k = B_{k|1},$$

$$r_k = \mathbf{W}_k^b \mathbf{n}_k - G \mathbf{w}_{k-1}, \quad \mathbf{W}_k = \left[ \mathbf{W}_k^b \mathbf{W}_k^c \right]. \quad (15b)$$

Since $\mathbf{W}_k^b$ is analogous to a linearly constrained Wiener filter [14, §2.5], its batch form is given by [14, §2]:

$$C_{\pi_k}^{-1} \mathbf{W}_k^b = \mathbf{A}_k \left( \mathbf{A}_k^H C_{\pi_k}^{-1} \mathbf{A}_k \right)^{-1} \left( B_{k|1} \right)^H + \left( I - \mathbf{A}_k \left( \mathbf{A}_k^H C_{\pi_k}^{-1} \mathbf{A}_k \right)^{-1} \mathbf{A}_k^H C_{\pi_k}^{-1} \right) C_{\pi_k}^{-1} G \mathbf{w}_{k-1}.$$n

that is, since $\mathbf{n}_k = \mathbf{n}_k$ and $\mathbf{A}_k = \mathbf{A}_k$:

$$C_{\pi_k}^{-1} \mathbf{W}_k^b = \mathbf{A}_k \left( \mathbf{A}_k^H C_{\pi_k}^{-1} \mathbf{A}_k \right)^{-1} \left( B_{k|1} \right)^H + \left( I - \mathbf{A}_k \left( \mathbf{A}_k^H C_{\pi_k}^{-1} \mathbf{A}_k \right)^{-1} \mathbf{A}_k^H C_{\pi_k}^{-1} \right) C_{\pi_k}^{-1} G \mathbf{w}_{k-1}.$$n

Therefore, (15a-15b) yields the following separable solutions:

$$\mathbf{W}_k^b = C_{\pi_k}^{-1} \mathbf{A}_k \left( \mathbf{A}_k^H C_{\pi_k}^{-1} \mathbf{A}_k \right)^{-1} B_{k|1} + C_{\pi_k}^{-1} \mathbf{A}_k \left( \mathbf{A}_k^H C_{\pi_k}^{-1} \mathbf{A}_k \right)^{-1} \mathbf{A}_k C_{\pi_k}^{-1} G \mathbf{w}_{k-1}, \quad (17)$$

leading to $\mathbf{x}_{k|k} = \left( \mathbf{A}_k^H C_{\pi_k}^{-1} \mathbf{A}_k \right)^{-1} \mathbf{A}_k C_{\pi_k}^{-1} \mathbf{y}_k = x_{1|k}$, and $E \left[ \left( \mathbf{A}_k^H \mathbf{w}_{k} - \mathbf{z}_k \right) \left( \mathbf{A}_k^H \mathbf{w}_{k} - \mathbf{z}_k \right)^H \right] = \left( \mathbf{A}_k^H C_{\pi_k}^{-1} \mathbf{A}_k \right)^{-1} \Delta \mathbf{P}_{1|k}.$n

Thirdly, the conditions (12) hold since: a) the noise sequences \{v_{l}\} and \{v_l\} are zero-mean, white, uncorrelated with known covariances $C_{v_l}$, and, b) $x_1' = x_1$ is uncorrelated with \{w_l, v_l\}. Based on these facts, the solution of (15a-15b) can also be computed recursively, since the LMDVF shares the same recursion as the KF [12][13]. Finally, $x_{1|k}$ (6) and $I_k$ (8b) can be computed recursively as follows:

$$I_k = x_{1|k}^H \mathbf{P}_{1|k}^{-1} x_{1|k}, \quad x_{1|k} = \left[ \begin{array}{c} 0 \ I \end{array} \right] \mathbf{x}_{k|k}, \quad \mathbf{P}_{1|k} = \left[ \begin{array}{c} 0 \ I \end{array} \right] \mathbf{P}_{k|k} \left[ \begin{array}{c} 0 \ I \end{array} \right]^H, \quad (18)$$

where $\mathbf{x}_{k|k}$ and $\mathbf{P}_{k|k}$ follow the recursion [12][13]:

$$\mathbf{x}_{k|k} = \left( \mathbf{I} - \mathbf{W}_k^b \mathbf{H}_k \right) \mathbf{x}_{k-1|k-1} + \mathbf{W}_k^b \mathbf{y}_k, \quad (19a)$$

$$\mathbf{P}_{k|k-1} = \mathbf{P}_{k|k-1} - \mathbf{F}_k \mathbf{w}_{k-1}^T + C_{w_{k-1}}, \quad (19b)$$

$$\mathbf{P}_{k|k} = \left( \mathbf{I} - \mathbf{W}_k^b \mathbf{H}_k \right) \mathbf{P}_{k|k-1}, \quad (19c)$$

except at time $k = 1$ where: $x_{1|1} = \mathbf{P}_{1|1} \mathbf{H}_1^H C_{v_1}^{-1} \mathbf{y}_1$, $\mathbf{P}_{1|1} = \left( \mathbf{H}_1^H C_{v_1}^{-1} \mathbf{H}_1 \right)^{-1}.$

3.3. Recursive form of $J_k$

Firstly, according to [15, 14, 17]:

$$[C_{\pi_k}] = \left[ \begin{array}{c} C_{\pi_{k-1}} & C_{\pi_{k-1,n_k}} \\ C_{\pi_{k-1,n_k}} & C_{n_k} \end{array} \right] = \left[ C_{n_k,\pi_{k-1-n_k}} \right] C_{n_k,\pi_{k-1}},$$

$$C_{n_k,\pi_{k-1-n_k}} = C_{n_k} - C_{\pi_{k-1,n_k}} C_{\pi_{k-1,n_k}}^{-1} C_{\pi_{k-1,n_k}},$$

$$C_{\pi_{k-1}} = C_{\pi_{k-1,n_k}} C_{\pi_{k-1,n_k}}^{-1} C_{\pi_{k-1},n_k}. $$
Secondly, according to (3b): \( C_{\pi_k} \triangleq C_{\pi_k} \) and \( C_{\pi_k} \triangleq C_{\pi_k} \). Therefore \( C_{\pi_k} \triangleq C_{\pi_k} \) can be computed by the KF recursion associated to the LDSS model resulting from the addition to (2a-2b) of the following initial state equation:

\[
x_1 = F_0 x_0 + w_0, \quad C_{x_0} = 0. \quad F_0 = I, \quad C_{w_0} = 0.
\]

Indeed then \( C_{\pi_k} \triangleq C_{\pi_k} \triangleq C_{\pi_k} \) by the KF recursion associated to the LDSS model resulting from (2a-2b) of the following initial state equation:

\[
x_1 = F_0 x_0 + w_0, \quad C_{x_0} = 0. \quad F_0 = I, \quad C_{w_0} = 0.
\]

Finally \( J_k \) can be computed recursively as:

\[
J_k = \ln |S_{k|k}| + J_{k-1}.
\]

4. MEASUREMENT OF THE BACKSCATTERING COEFFICIENT OF A TARGET

Let us consider a radar system consisting of a 1-element antenna array receiving scaled, time-delayed, and Doppler-shifted echoes of a known complex bandpass signal \( e_T(t) e^{j2\pi f_c t} \), where \( f_c \) is the carrier frequency and \( e_T(t) \) is the envelope of the emitted signal. The antenna receives a pulse train (burst) of \( L \) pulses with a pulse repetition interval \( T \), backscattered by a “slow” moving target [16] (no range migration during the burst and the Doppler effect on \( e_T(t) \) is negligible). The target is assumed to have a radial motion towards the radar with an imposed constant radial speed \( v \) (\( r(t) = r_0 + vt \)) and a constant aspect angle, which leads to a constant complex backscattering coefficient \( \rho \) along the trajectory. At observation time \( t_1 \), a simplified observation model at the output of the range matched filter is given by [16]:

\[
y_1 = h_t (\nu) \beta x_{1-1} + v_1, \quad x_1 = f x_{1-1} + w_{1-1}, \quad x_1 = \frac{p}{r_1}.
\]

Secondly, due to adverse wind conditions, the true velocity of the target may differ from the desired one, and therefore the normalized Doppler frequency \( \theta \) must be estimated as well. In this setting, the joint estimation of \( (x_1, \theta) \) in the ML sense leads to GCMLEs \( \hat{x}_{1|k} \) and \( \hat{\theta}_{k} \) (6-8a), which MSEs are displayed respectively on figures (1) and (2), where \( L = 10, \theta = 0.1, x_1 = (1 + j) / (2\sqrt{2}) \), and \( f = 1.01 \), which means that the range of the target changes significantly as the number of observations increases (1 \( \leq k \leq 120 \)). GCMLEs \( \hat{x}_{1|k} \) and \( \hat{\theta}_{k} \) are obtained via the recursive form of \( x_{1|k} (\theta), \hat{x}_{k} (\theta) \) and \( \hat{\theta}_{k} (\theta) \) computed over a discretization of \( [-1, 1] \) with a step of \( 0.1 \). The empirical MSEs are assessed with \( 210^4 \) Monte-Carlo trials. In order to highlight the impact of a target fluctuation on GCMLEs, we consider two cases with small fluctuations (\( \sigma^2_{\omega_1} = \sigma^2_{\omega_2} \in \{10^{-4}, 10^{-3}\} \) and, for comparison, we also provide the ideal case with no fluctuation (\( \sigma^2_{\omega_1} = 0 \)) and the associated well known conditional Cramér-Rao bound (CRB) for \( \theta \) and \( x_1 \). Figure (1) and (2) exemplifies the non negligible impact of a target fluctuation on the MLEs asymptotic performance which introduces a lower limit in the achievable MSE. Practically speaking, this lower limit shows that, when a target fluctuates, there exists an optimal number of observations that can be combined coherently in order to estimate its parameters with a nearly minimum achievable MSE. Theoretically speaking, we exhibit non consistent MLEs when the number of observations tends to infinity, which highlights the consequence of combining (even slightly) dependent observations.
